

## INFRARED TIRE TEMPERATURE SENSOR IRTS-V2

The Izze-Racing tire temperature sensor is specifically designed to measure the highly transient surface temperature of a tire with spatial fidelity, providing invaluable information for chassis tuning, tire exploitation, compound selection, and driver development.

The sensor is capable of measuring temperature at 16, 8, or 4 laterally-spaced points, at a sampling frequency of up to 100Hz, object temperature between -20 to 300°C, using CAN 2.0A protocol, and enclosed in a compact IP66 rated aluminum enclosure.

The sensor is available with two field-of-views: ultra-wide (120°) or wide (60°).

### ADDITIONAL INFORMATION:

- Stated accuracy is under isothermal package conditions; for utmost accuracy, avoid abrupt temperature transients and gradients across the sensor's package.
- Point the sensor in the downstream direction (facing front of tire) to avoid contamination, pitting, and/or destruction of the sensor's lens from debris. Protective windows are available upon request.
- The *effective* emissivity of most tires ranges from approximately 0.75 to 0.90 in the 8 to 14  $\mu\text{m}$  spectrum.
  - Generally, the emissivity should be lowered as the standoff distance (distance from tire to sensor) increases; this is particularly important with the 60° FOV sensor due to the larger standoff distances required. The suggested emissivity vs. standoff distance is shown in the graph below:

- Lowering the emissivity increases the measured object temperature and vice versa
- Noise Equivalent Temperature Difference (NETD) increases with increasing sampling frequency:
  - Provided that tire surface temperature is highly transient, it is usually advantageous to use a higher sampling frequency at the cost of increased noise. A sampling frequency of 16 or 32 Hz is recommended for most applications.
